摘要 【目的】目前致密砂岩中石英颗粒溶蚀现象受到越来越多的重视,但石英颗粒边界溶蚀特征与溶蚀机制的关系尚不清晰。【方法】基于薄片鉴定、阴极发光和扫描电镜观察等方法,结合测试分析数据,对川西地区须家河组二段石英溶蚀后颗粒边界特征进行了精细观察与统计分析。【结果】石英颗粒边界溶蚀特征划分为两类:(1)边界光滑—溶蚀增孔型,表现为石英颗粒边界光滑清晰,被溶蚀后形成孔隙;(2)边界模糊—溶蚀交代型,表现为石英颗粒边界模糊粗糙,被碳酸盐矿物和黏土矿物溶蚀交代,根据交代矿物不同进一步划分为边界模糊—溶蚀—碳酸盐交代型和边界模糊—溶蚀—黏土矿物交代型。其中边界光滑—溶蚀增孔型为酸性条件下有机酸溶蚀的结果,边界模糊—溶蚀—碳酸盐交代型为碱性条件下离子浓度差发生碳酸盐交代。边界模糊—溶蚀—黏土矿物交代型为碱性条件下“盐效应”的催化,并通过黏土薄膜交代。石英颗粒溶蚀边界演化趋向于由边界光滑—溶蚀增孔型向边界模糊—溶蚀交代型转变。研究区须二段石英颗粒溶蚀面孔率范围介于2.05%~4.09%,平均为3.19%。【结论】石英颗粒的溶蚀作用可提供一定量的次生孔隙,增加油气储集空间,有效改善致密砂岩的孔隙结构。

0 引言

前人在致密砂岩储层及优质储层的研究中,主要聚焦在长石、岩屑等铝硅酸盐溶蚀及碳酸盐胶结物等成岩作用的研究^[1-2],而石英作为稳定的矿物,普遍认为很难被溶蚀形成有效的孔隙。随着研究的不断深入,发现致密砂岩储层中不仅发育长石以及其他易溶矿物溶孔,还发育石英溶孔^[3-5]。不同学者对石英的溶蚀现象也进行了一系列研究,并提出多种石英溶蚀机制及溶蚀边界形态。比如:在碱性环境下,石英颗粒的溶蚀速率增加, SiO_2 在 OH^- 的影响下易发生溶蚀,形成港湾状边界特征等^[6-12];在酸性条件下,有机酸能使 SiO_2 形成络合物从而使得石英发生溶蚀,使石英形成凹凸边界特征^[13-17];以及在碱金属离子的影响下,能削弱 SiO_2 的Si-O-Si键的强度从而溶蚀石英,形成港湾状和锯齿状边界特征等^[18-20]。可

以看出,石英颗粒溶蚀边界特征与溶蚀机制之间具有明显的相关性,但其耦合关系尚未有系统性总结,导致难以判断石英溶蚀的类型及特征。因此,有必要开展石英颗粒溶蚀边界形态与溶蚀机制及对储层地质意义的研究。

四川盆地上三叠统须家河组发育典型的致密砂岩储层,近年来众多学者对须家河组储层砂岩组构和成岩演化等方面开展了大量研究,认为主要储集空间类型为长石、岩屑等易溶组分溶蚀后所形成的孔隙^[21-27]。须家河组成岩流体演化过程中,酸碱度变化频繁^[28]。同时,研究过程中发现川西地区须家河组二段(须二段)石英溶蚀现象普遍存在,且石英颗粒边界具有多种溶蚀形态。因此,开展须二段石英溶蚀的研究具有代表性意义。基于薄片鉴定、阴极发光和扫描电镜观察等方法,结合测试分析数

据,对须二段石英边界溶蚀特征进行精细观察与统计分析,通过建立不同石英边界溶蚀类型,厘定石英的溶蚀过程,进行溶蚀机理分析,可以为砂岩骨架颗粒溶蚀分析及致密砂岩中孔隙成因提供新的思路 and 参考。

1 地质背景

四川盆地位于青藏高原东侧、扬子板块西北侧,是一个多旋回的沉积盆地^[29-32]。从震旦纪到中三叠世,盆地为一套海相沉积;在中三叠世末期,受到印支运动的影响,特提斯洋的海水退出四川,四川盆地大多地层受到不同程度剥蚀,盆地由海盆逐渐转变为陆盆^[33-34];到了晚三叠世,在印支运动的持续影响下,板块之间发生挤压碰撞,使得一些海相地层隆起并遭受剥蚀,发生沉积超覆现象,四川盆地由海相沉积过渡为陆相沉积^[35-36]。川西新场地区须家河组就是在此构造背景下形成的(图1),自下而上划分成六个岩性段,须三段和须五段以煤系地层为主,发育灰黑色泥页岩夹砂岩,须二、须四和须六段以砂岩为主,发育岩屑石英砂岩夹灰黑色泥页岩,须一段则发育一套海陆交互的地层组合^[38]。

其中川西新场地区须二段继承了须一段的沉积格局,发育一套海陆过渡三角洲沉积物,沉积了从下

至上岩屑砂岩—岩屑石英砂岩—岩屑砂岩夹互层序列组合,相比其他段,须二段的石英含量相对较高^[39]。

2 石英颗粒边界溶蚀形态特征

基于川西新场地区须二段典型取心井新10和新5等井近200块岩心样品,开展了薄片鉴定等分析。观察结果表明,须二段岩性以岩屑砂岩和岩屑石英砂岩为主,有少量的石英砂岩和长石石英砂岩。石英的含量介于45%~96%,平均为75.3%;长石含量较少,部分被溶蚀,含量介于1%~34%,平均为6.5%;岩屑含量介于6%~32%,平均为18.2%,岩屑中主要以沉积岩岩屑和变质岩岩屑为主,少量岩浆岩岩屑,其中变质岩岩屑中硅质岩屑含量较多,以燧石和变质石英岩岩屑为主。除了骨架颗粒之外,还发育少量自生矿物和胶结物,包括多期次的方解石胶结、自生白云石胶结、硅质胶结等,含量介于7%~9%;杂基含量较少,一般小于3%,以泥质为主,含少量云母及黏土矿物(图2a)。

在须家河组二段高石英、低长石、少杂基结构特征背景下,结合扫描电镜及阴极发光特征,对须二段石英颗粒溶蚀特征进行了分析。特征如表1所示,石英颗粒普遍发生溶蚀(图2a),并形成多种边界形态及特征。

表1 石英颗粒边界溶蚀特征

Table 1 Dissolution characteristics of quartz grain boundary

边界形态	边界特征	溶蚀特征描述	举例
凹凸状	边界清晰光滑	偏光显微镜下,石英发生溶蚀后,被溶蚀边界光滑清晰,呈凹凸状,形成孔隙	图2b
雨痕状	边界清晰光滑	扫描电镜下,石英发生溶蚀后,被溶蚀许多凹坑,呈雨痕状,形成微型孔隙	图2c,d
港湾状	边界清晰	偏光显微镜下和扫描电镜下,溶蚀后,被溶蚀边界清晰,呈港湾状,溶蚀形成的孔隙被黏土矿物和碳酸盐矿物充填	图2e,f,h,i
蜂窝状	边界清晰	扫描电镜下,溶蚀后,边界清晰,呈蜂窝状,溶蚀形成的孔隙被黏土矿物充填	图2g
锯齿状	边界模糊,粗糙	偏光显微镜下和扫描电镜下,溶蚀后,被溶蚀边界模糊、粗糙,呈锯齿状,在阴极发光下可看出边界与黏土矿物或碳酸盐矿物发生物质交换	图2j-l

根据石英颗粒边界溶蚀形态及特征,将其边界类型分为两大类(图2,3)。

(1) 边界光滑—溶蚀增孔型:石英颗粒边界被溶蚀,边界光滑清晰,呈凹凸状(图3a,d),形成微小孔隙(图2b),在扫描电镜下表现为颗粒表面的雨痕状溶蚀特征(图2c,d),在后续的成岩过程中,石英颗粒被溶蚀后所形成的孔隙会被黏土矿物或碳酸盐矿物充填(图2e,f),电镜下能观察到黏土矿物为伊利石和绿泥石(图2g~i)。

(2) 边界模糊—溶蚀交代型:石英颗粒被黏土矿物或碳酸盐胶结物溶蚀交代,从而破坏了原有的边界特征,导致石英边界模糊粗糙(图2j,k),呈锯齿状。通过扫描电镜观察,与石英颗粒发生溶蚀交代的矿物主要是黏土矿物以及少量铁方解石(图2l)。因此,根据交代矿物的不同,进一步划分为两类,分别为边界模糊—溶蚀—碳酸盐交代型(图3b,e)、边界模糊—溶蚀—黏土矿物交代型(图3c,f)。

3 不同石英颗粒边界溶蚀成因

石英颗粒不同边界溶蚀形态类型,具有不同的物质交换特征,也代表了不同的溶蚀成因过程。

3.1 边界光滑—溶蚀增孔型成因

研究区该类溶蚀边界发育较少,以颗粒原有边界特征相对完整,光滑清晰,基本没有被溶蚀破坏为

典型表现形式(图2b,c)。颗粒表面多呈现雨痕状溶蚀,代表了石英颗粒处于一个较弱的溶蚀环境。该类溶蚀特征在大牛地气田上古生界储层中也有发现,普遍认为这类“雨痕状”溶坑是处于溶蚀作用较弱或者是溶蚀时间较短的溶蚀环境的结果^[16-17]。

实验结果表明,在酸性溶液下,温度达到200℃以上时,石英颗粒表面才开始发生微弱的溶蚀^[16]。结合四川盆地的地温梯度和包裹体的均一温度,须二段地层温度在地质历史时期普遍达不到200℃^[28],故须二段石英颗粒难以在酸性条件下发生溶蚀。然而,前人在实验室进行了有机酸对石英颗粒溶解速率及机理研究,发现草酸等有机酸的加入会使石英颗粒的溶解速度提高^[13,15,19],但不会增加石英的溶解度^[11,14,40]。然而在有机酸环境中,二氧化硅会与有机酸发生反应,H⁺链接到二氧化硅的Si-O-Si键上形成络合物H₄SiO₄,从而降低酸性条件下的反应活化能,并且生成的络合物扩散到地层水中,从而使得反应正向进行,加快石英颗粒的溶解^[18]。

四川盆地须家河组在早成岩期有机质开始成熟^[28],提供了一个富含有机酸的成岩环境,有机酸能起到提高石英溶解速率的催化作用,使得研究区须二段石英颗粒发生溶蚀(图4)。但这个过程属于弱溶蚀,主要表现为石英颗粒边界局部开始发生溶蚀的过程,并提供微小的孔隙(图2b)。边界光滑—溶蚀增孔型为石英颗粒边界发生有机酸溶蚀成因。

(a) 4 880.54 m, lithic quartz sandstone; (b) 4 935.04 m, lithic quartz sandstone

3.2 边界模糊—溶蚀交代型成因

前人对碱性条件下石英溶解机制的研究中^[6,20,41],认为石英在碱性环境下受OH⁻的催化作用,溶解速率会随着pH值的增加而增加。同时,电解质的“盐效应”会降低石英颗粒的活化能,从而提高溶解速率。前人在实验中证实了石英颗粒在碱性条件下有电解质的参与,会提高石英溶解速率^[3,5]。

川西新场地区须二段石英颗粒溶蚀现象普遍存在,其中溶蚀边界外存在的黏土矿物主要为伊利石和绿泥石(图2g, h),样品中高岭石和伊/蒙混层较少甚至没有(表2),另有少量具碱性成岩环境指示意义的碳酸盐胶结物(图2e)。伊利石和绿泥石的形成需要富含K⁺、Fe²⁺和Mg²⁺的碱性环境^[42-44],蒙脱石具有在碱性条件下向伊利石或绿泥石转化的特征,这几类黏土矿物的存在也是反映当时碱性成岩环境的标志。

同时,在扫描电镜下观察发现须二段砂岩中存

表2 黏土矿物相对含量

Table 2 Relative content of clay minerals

样品井号	深度/m	黏土矿物相对含量/%			
		伊利石	高岭石	绿泥石	伊/蒙混层
川合100井	4 337.65	81	3	12	4
新场5井	4 740.33	81	7	12	0
新场10井	4 852.84	78	0	22	0
新场10井	4 880.54	65	0	35	0
新场5井	4 933.35	72	10	18	0
新场10井	4 937.80	61	0	39	0

在少量石盐矿物(图5),表明孔隙中存在NaCl电解质溶液。此外,黏土矿物中伊利石和绿泥石的存在,也指示了流体中具有K⁺、Fe²⁺和Mg²⁺。以上几类电解质在碱性环境下,提高了成岩流体对石英溶解的速率,使得石英颗粒边界发生较强烈溶蚀的同时,伴随着黏土矿物和碳酸盐矿物的溶蚀交代。研究区石英颗粒主要发育两种类型的溶蚀交代,其成因如下。

1) 边界模糊—溶蚀—碳酸盐交代型

此类边界溶蚀常伴随着碳酸盐胶结物的生成,表现为碳酸盐矿物破坏石英颗粒原有边界,使边界模糊粗糙,呈锯齿状,这类现象在塔中地区亦有发育。钟大康等^[9]在塔中地区发现石英颗粒边界被碳酸盐矿物交代,并且解释这类现象发生在偏碱性环境。其过程表现为石英表面发生溶蚀,溶解形成的SiO₂以H₄SiO₄分子的形式向孔隙水扩散,孔隙水中Ca²⁺和HCO₃⁻浓度如果高于H₄SiO₄,则会因为浓度差发生扩散,从而导致碳酸盐矿物对石英颗粒发生交代。这与研究区须二段石英溶蚀特征一致,并且在镜下还观察到石英颗粒被铁方解石和铁白云石交代,认为在碱性条件下,铁方解石和铁白云石释放出的Fe²⁺提高了石英的溶蚀速率,使得孔隙中Ca²⁺和HCO₃⁻浓度普遍高于H₄SiO₄,形成浓度差,从而发生碳酸盐矿物对石英颗粒的溶蚀交代(图6)。

2) 边界模糊—溶蚀—黏土矿物交代型

该类型在研究区较为常见,是黏土矿物溶蚀交

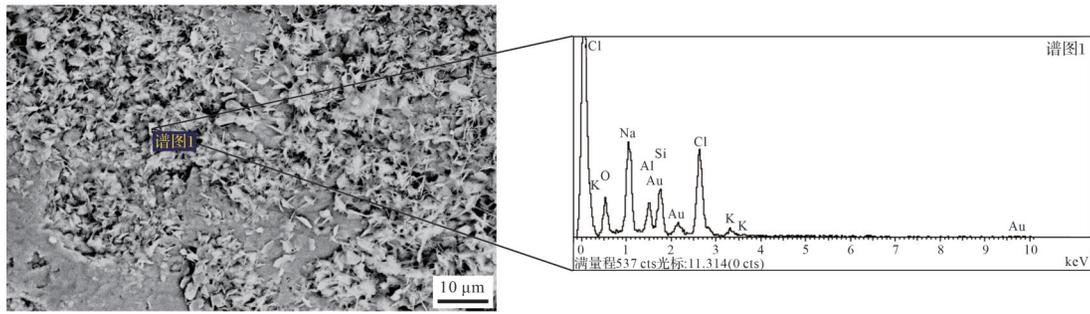

图5 须二段中见石盐(扫描电镜及能谱,新10井,4 931.40 m,岩屑砂岩)

Fig.5 Shale salt in the second member of the Xujiahe Formation (scanning electron microscope and energy spectrum, well Xin 10, 4 931.40 m, lithic sandstone)

代的结果。该类石英颗粒边界被交代破坏,边界呈不清晰的锯齿状。前人研究认为,在富含CO₂的孔隙水中,黏土矿物的存在能游离出K₂CO₃,形成局部强碱环境,使石英颗粒发生溶解,溶解的物质通过黏土矿物膜扩散而走,从而交代石英颗粒^[45]。刘金库等^[20]在川南须家河组储层研究中,认为黏土矿物溶蚀交代与黏土矿物的强吸附性有关,可在黏土矿物表面吸附电解质从而形成“盐效应”,加速石英颗粒溶蚀。笔者在镜下观察到石英颗粒被伊利石和绿泥石混层交代的锯齿状边界(图21),认为是在碱性成岩环境,孔隙中含有Fe²⁺、K⁺和Mg²⁺等离子,所产生“盐效应”提高了石英颗粒的溶蚀速率,在离子浓度差的驱动下,通过黏土矿物薄膜对石英颗粒进行溶蚀交代,形成此类边界(图7)。

4 石英颗粒溶蚀地质意义

4.1 石英颗粒边界溶蚀演化特征及意义

对石英颗粒溶蚀边界的研究发现,黏土矿物和碳酸盐矿物组合能反映出导致石英溶蚀的成岩流体演化特征。镜下观察到至少两期次的碳酸盐矿物,为方解石和白云石组合以及铁方解石和铁白云石组合。前人研究认为,川西坳陷须家河组发育早期方解石和晚期铁方解石、铁白云石组合,说明成岩期至少经历两个碱性成岩流体演化时期^[24,28]。但是高岭石的生成主要来自有机酸环境中的长石溶蚀^[23],并且由于须二段K⁺/H⁺活度比较高,使得部分层段的长石又得到了有效保存。这不仅说明须家河组经历了酸性成岩流体过程,还解释了长石含量变化范围广的原因。比如统计须二段长石含量介

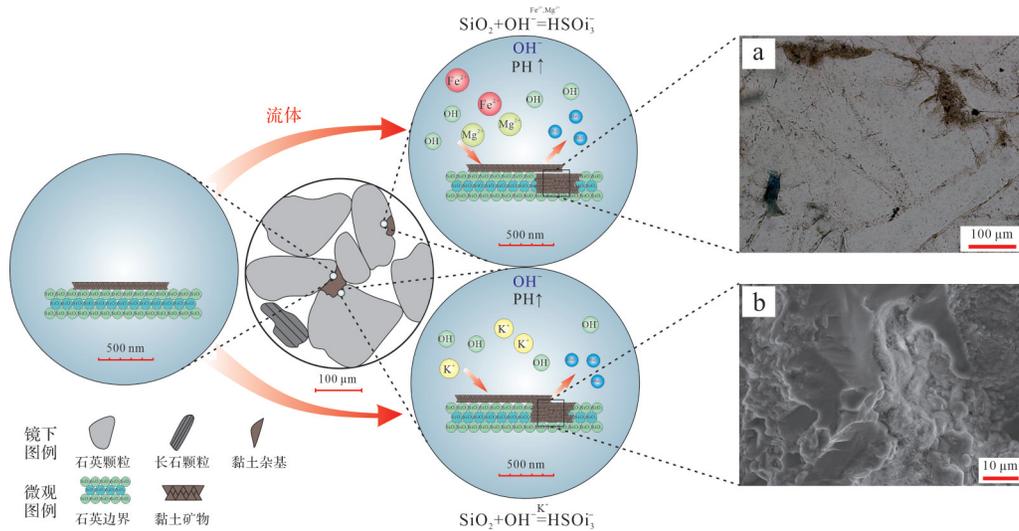

图7 边界模糊—溶蚀—黏土矿物交代型成因图(新10井)

(a)4 880.54 m,岩屑石英砂岩;(b)4 852.84 m,岩屑石英砂岩

Fig.7 Genesis diagram of fuzzy boundary-dissolution clay mineral metasomatic type in lithic quartz sandstone at well Xin 10

(a) 4 880.54 m, lithic quartz sandstone; (b) 4 852.84 m, lithic quartz sandstone

于1%~34%,平均为6.5%。表2多个样品中高岭石含量几乎为零,基本转化为伊利石,说明酸性成岩环境之后又转化为碱性环境。因此,须家河组成岩流体表现为从初期的弱碱性变为酸性再到碱性的演化特征^[28,31,46]。

须二段成岩流体弱碱性—酸性—碱性交替的演化特征,使石英颗粒发生不同类型的溶蚀,并形成不同类型的石英颗粒溶蚀边界。结合溶蚀边界特征发

现,边界光滑—溶蚀增孔型石英颗粒边界为有机酸溶蚀成因,而边界模糊—溶蚀—碳酸盐交代型和边界模糊—溶蚀—黏土矿物交代型则是碱性环境溶蚀的结果,并且石英颗粒在碱性条件下没有碱金属离子的参与时不易发生溶蚀^[8-9]。因此,可以认为石英颗粒先发生边界光滑—溶蚀增孔型溶蚀后发生边界模糊—溶蚀—碳酸盐交代型和边界模糊—溶蚀—黏土矿物交代型溶蚀(图8)。

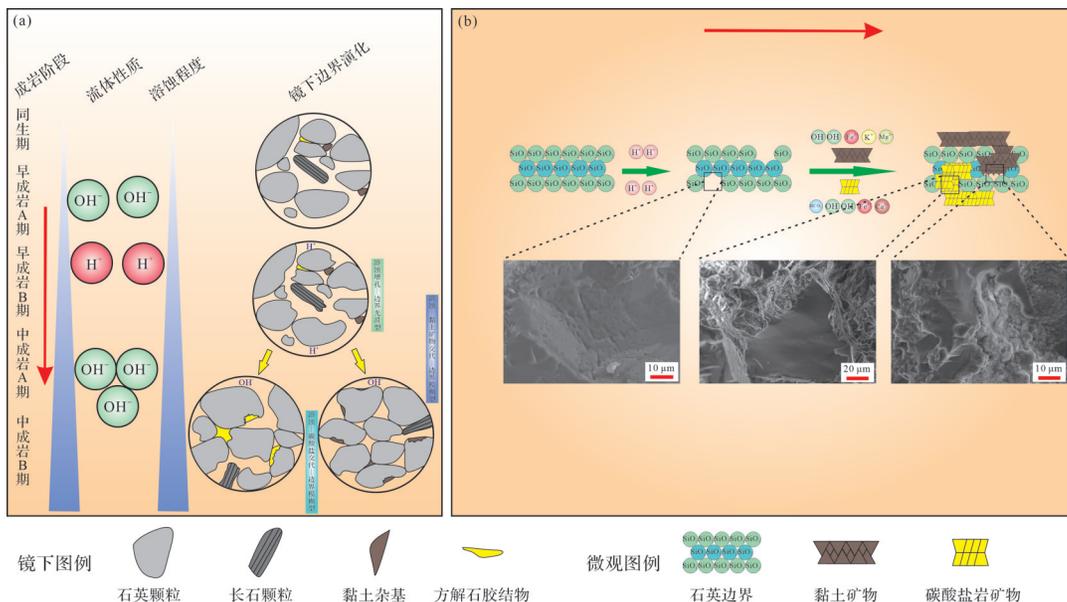

图8 石英颗粒边界溶蚀演化图

(a)边界演化过程;(b)微观边界演化过程

Fig.8 Evolution diagram of quartz particle boundary dissolution

(a) process of boundary evolution; (b) process of micro-scale boundary evolution

在研究石英溶蚀演化的图2f中观察到石英颗粒溶蚀形成的孔隙被碳酸盐和黏土矿物充填,边界从光滑逐步变粗糙模糊,有发生溶蚀交代的趋势(图2f)。这可能是在酸性条件下发生边界光滑—溶蚀增孔型溶蚀,后进入碱性环境时孔隙开始被其他矿物充填,最后发生边界模糊—溶蚀—碳酸盐交代型和边界模糊—溶蚀—黏土矿物交代型溶蚀(图8)。

边界模糊—溶蚀—碳酸盐交代型和边界模糊—溶蚀—黏土矿物交代型这两类溶蚀中,碳酸盐矿物对石英溶蚀边界交代溶蚀难以释放储集空间,故此类型溶蚀对储层建设性作用较小^[19],而黏土矿物对石英溶蚀边界的交代溶蚀可以解放出部分储集空间^[20],因而对储层建设贡献较大。须二段中碳酸盐交代石英边界型溶蚀较少,而黏土矿物交代石英边界型溶蚀较多。这表明,石英颗粒继续溶蚀可对储层起更积极的建设性作用。

石英颗粒边界演化最终向边界模糊—溶蚀—碳酸盐交代型和边界模糊—溶蚀—黏土矿物交代型转变,这不仅揭示了边界光滑—溶蚀增孔型少的成因,也反映了石英颗粒边界演化是往对储层有利的方向进行。

4.2 石英溶蚀作用对次生孔隙的建设性意义

在对边界溶蚀特征的研究中,发现研究区石英颗粒溶蚀现象普遍。定量统计了新10井和新5井薄片石英颗粒发生溶蚀的情况(图9),发现须二段对储层建设贡献较大的溶蚀边界含量较多,故统计石英溶蚀面孔率仍具有积极意义。为统计石英溶蚀面孔率,对被溶蚀石英颗粒进行颗粒形态恢复,然后比较溶蚀后形态,根据颗粒切片面积差异估算石英颗粒被溶蚀的比例(图10)。在统计石英溶蚀面孔率时,为提高统计准确度,需要将石英压溶作用及粒间溶孔的影响剔除,并且排除长石溶蚀的影响。

统计结果表明,须二段砂岩中石英颗粒发生溶蚀比例较高。在发生溶蚀的石英颗粒中,溶蚀缺失部分占石英颗粒面积的4.33%~8.67%,平均为6.37%。发生溶蚀的石英颗粒占石英全部颗粒的比例达到55.33%以上,最大约72%,平均为63.02%。石英在薄片中的含量介于45%~96%,平均为75.3%。因此,石英溶蚀面孔率统计结果为2.05%~4.09%,平均为3.19%。将得到的溶蚀面孔率数据与实测孔隙度进行相关性耦合分析,溶蚀面孔率和孔隙度呈正相关,线性相关系数 R^2 为0.7926(图11),具有明显相关性,表明石英颗粒溶蚀作用的发育有效地改善了

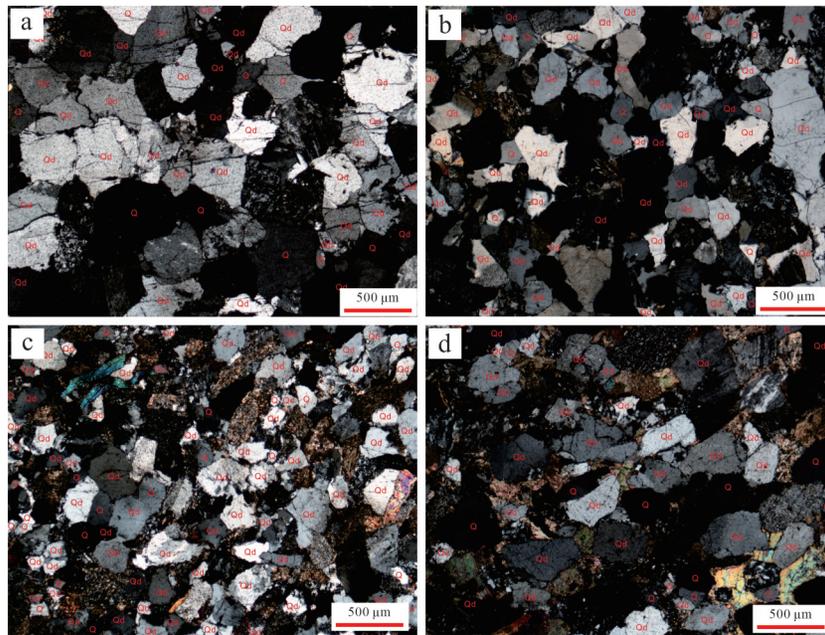

图9 石英溶蚀比例统计

(a)新10井,4 880.54 m,岩屑石英砂岩;(b)新10井,4 935.04 m,岩屑石英砂岩;(c)新5井,4 737.20 m,岩屑砂岩;(d)新5井,4 746.44 m,岩屑砂岩;Q.未溶蚀石英颗粒;Qd.被溶蚀石英颗粒

(a) 4 931.40 m, lithic quartz sandstone; (b) 4 935.04 m, lithic quartz sandstone

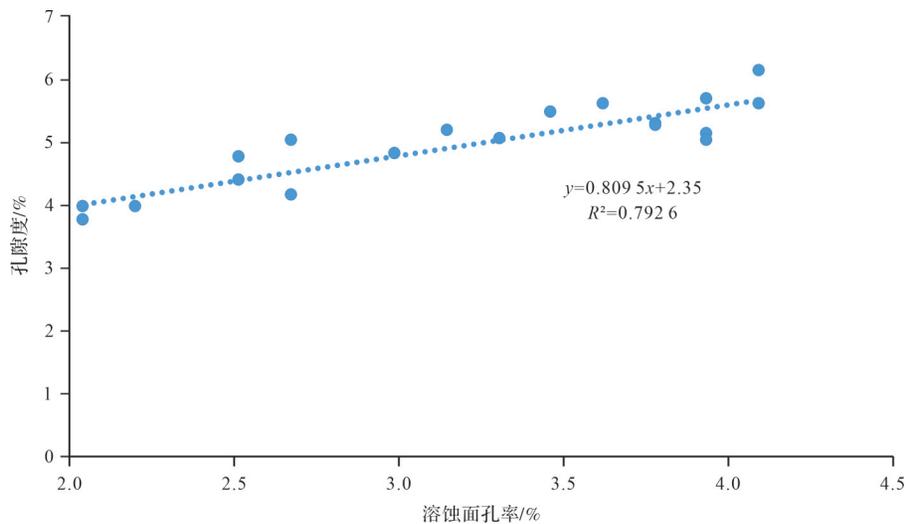

图11 溶蚀面孔率与孔隙度关系

Fig.11 Relationship between dissolution surface porosity and porosity

储层物性。于雯泉等^[15]对金湖凹陷的石英溶蚀面孔率进行统计计算,得到溶蚀面孔率最大能达到20%。在庞大的石英颗粒基数下,石英颗粒的溶蚀作用能提供一定量的孔隙度,可以有效增加致密砂岩的储集空间,并且改善储层的孔隙结构,提高储层孔隙性能。

尽管须二段发生溶蚀的石英颗粒占比较高,但是石英颗粒被溶蚀的程度普遍较小,不同溶蚀颗粒边界对须二段砂岩储层中次生孔隙的意义具有明显差异(图12)。石英颗粒溶蚀比例与溶蚀形成的次生孔隙呈正相关关系,石英颗粒含量与溶蚀比例具负相关关系,这与石英颗粒的基数较高而溶蚀颗粒数量相对稳定有关。所以河口坝石英含量相对较高,石英溶蚀比例较低;水下分流河道石英颗粒含量相对较低,而溶蚀比例较高。因此,沉积微相

与石英溶蚀比例具有一定的相关性,这为不同地区不同沉积微相所发育的石英溶蚀现象提供新的参考。

5 结论

(1) 石英颗粒边界溶蚀可划分为两大类,即边界光滑—溶蚀增孔型和边界模糊—溶蚀交代型,基于溶蚀交代矿物的不同,后者可进一步划分为边界模糊—溶蚀—碳酸盐交代型和边界模糊—溶蚀—黏土矿物交代型。

(2) 边界光滑—溶蚀增孔型为酸性条件下有机酸促进石英颗粒溶蚀的结果。边界模糊—溶蚀交代型则发生在碱性条件下,当存在离子浓度差,可导致碳酸盐矿物发生溶蚀交代;或者由于黏土矿物产生

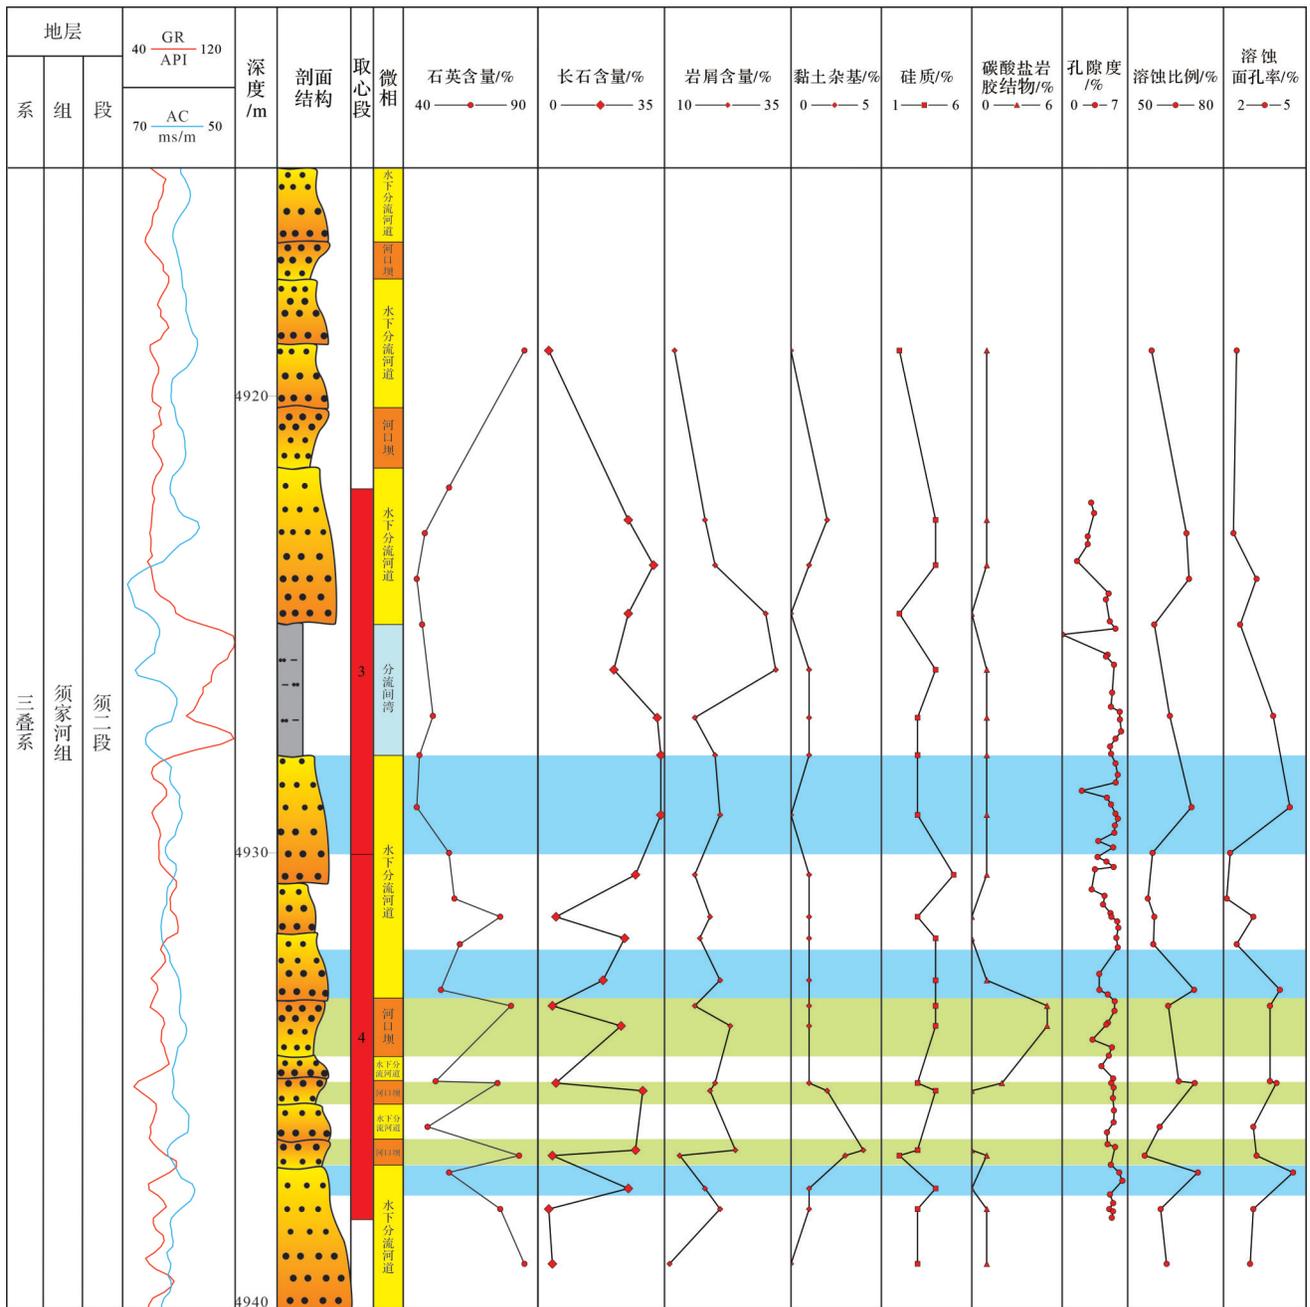

图12 新10井综合柱状图

Fig.12 Comprehensive histogram of well Xin 10

“盐效应”,提高了石英颗粒溶蚀速率,并通过黏土矿物薄膜发生黏土矿物溶蚀交代。

(3) 石英颗粒边界演化的趋势是向边界模糊—交代型并且对储层有利的方向进行。统计表明,石英溶蚀面孔率介于2.05%~4.09%,平均为3.19%。石英颗粒溶蚀可以增加油气储集空间,有效改善致密砂岩的孔隙结构。

致谢 感谢两位评审专家提出的宝贵意见和建议,感谢编辑部老师们为论文进行评审和校正。

Abstract: [Objective] There is a clear correlation between the boundary condition of quartz particles and their dissolution. This relationship is systematically summarized here to determine the types and characteristics of quartz dissolution. [Methods] Thin section identification, cathodoluminescence and scanning electron microscopy were used in combination with detailed observation and statistical analysis to determine the quartz boundary dissolution characteristics in rock from the second member of the Xujiahe Formation, western Sichuan. The processes of different types of quartz boundary dissolution were determined and the mechanisms were analyzed. The study provides new ideas and references for dissolution analysis in sandstone skeleton particles, and the genesis of pores in tight sandstone. [Results] Two types of boundary dissolution in quartz particles were revealed: (1) smooth boundary-dissolved pore-increasing, in which the boundary of the quartz particles is seen to be smooth and clear, and pores are formed after dissolution; and (2) fuzzy metasomatic boundary dissolution seen as indistinct and rough quartz particle boundaries caused by the presence of dissolved and metasomatized carbonates or clay minerals producing either fuzzy boundary-dissolution carbonates or fuzzy boundary-dissolution clay minerals. Type 1 is the result of organic acid dissolution in acidic conditions. Type 2 metasomatism between carbonate ions and quartz particles is due to differences in ion concentration in alkaline conditions. Clay mineral metasomatism occurs when alkaline metal ions are released to produce a 'salt effect', accelerating the dissolution rate of quartz particles. Metasomatized quartz particles are covered with a clay film. The dissolution boundaries of the quartz particles tend to change from type 1 to type 2; the alteration favors the formation of a hydrocarbon reservoir. Quartz particles in the second member of the Xujiahe Formation in the study area had a surface area corrosion loss of 4.33%-8.67% (average 6.37%). Up to 72% of all quartz particles showed dissolved surfaces, averaging 63.02%. The quartz content in thin sections was about 45%-96% (average 75.3%). A statistical analysis of the results showed quartz dissolution surface porosity between 2.05% and 4.09% (average 3.19%; $R^2 = 0.7926$). [Conclusions] The proportion of partially dissolved quartz particles effectively alters the pore structure of tight sandstone, thus favoring reservoir development by providing a reasonable amount of secondary pores and increasing reservoir space for oil and gas.
